6.1 INTRODUCTION :

Urbanisation is never ~~and~~ even process as some cities grow at more a rapid rate than others. The process of urbanisation reflects the spatial geographical characteristics of the region. The rank size rule was first develop by Zipf (1949), and later on it was evaluated by H.A.Simon (1955), C.T.Stewart (1968), B.J.L.Berry and W.L.Garison (1958) and N.B.K.Reddy (1969).

The rank size rule is an investigative hypothesis, a theoretical model or a norm to express the relationship of the often observed empirical regularities in the city size. It present a generalised picture of urban settlement in a region. "The belief that cities are related to each other in some orderly way forming into a system, is the basis for the postulation of rank size rule," (N.B.K.Reddy,1969). To identifying whether the rank size rule (zipf,1949) is applicable in the study region or not, it has been applied to find out the actual size distribution of urban centres in the study region.

The rank size rule which states that if all the urban centres in an area are ranked in a descending order of population of n^{th} town will be $1/n^{\text{th}}$. The size of the largest city and the population of other urban centres will be arranged according to series $1, 1/2, 1/3, 1/4 \dots 1/n^{\text{th}}$. This is, if the population of the n^{th} city is multiplied by its rank. It

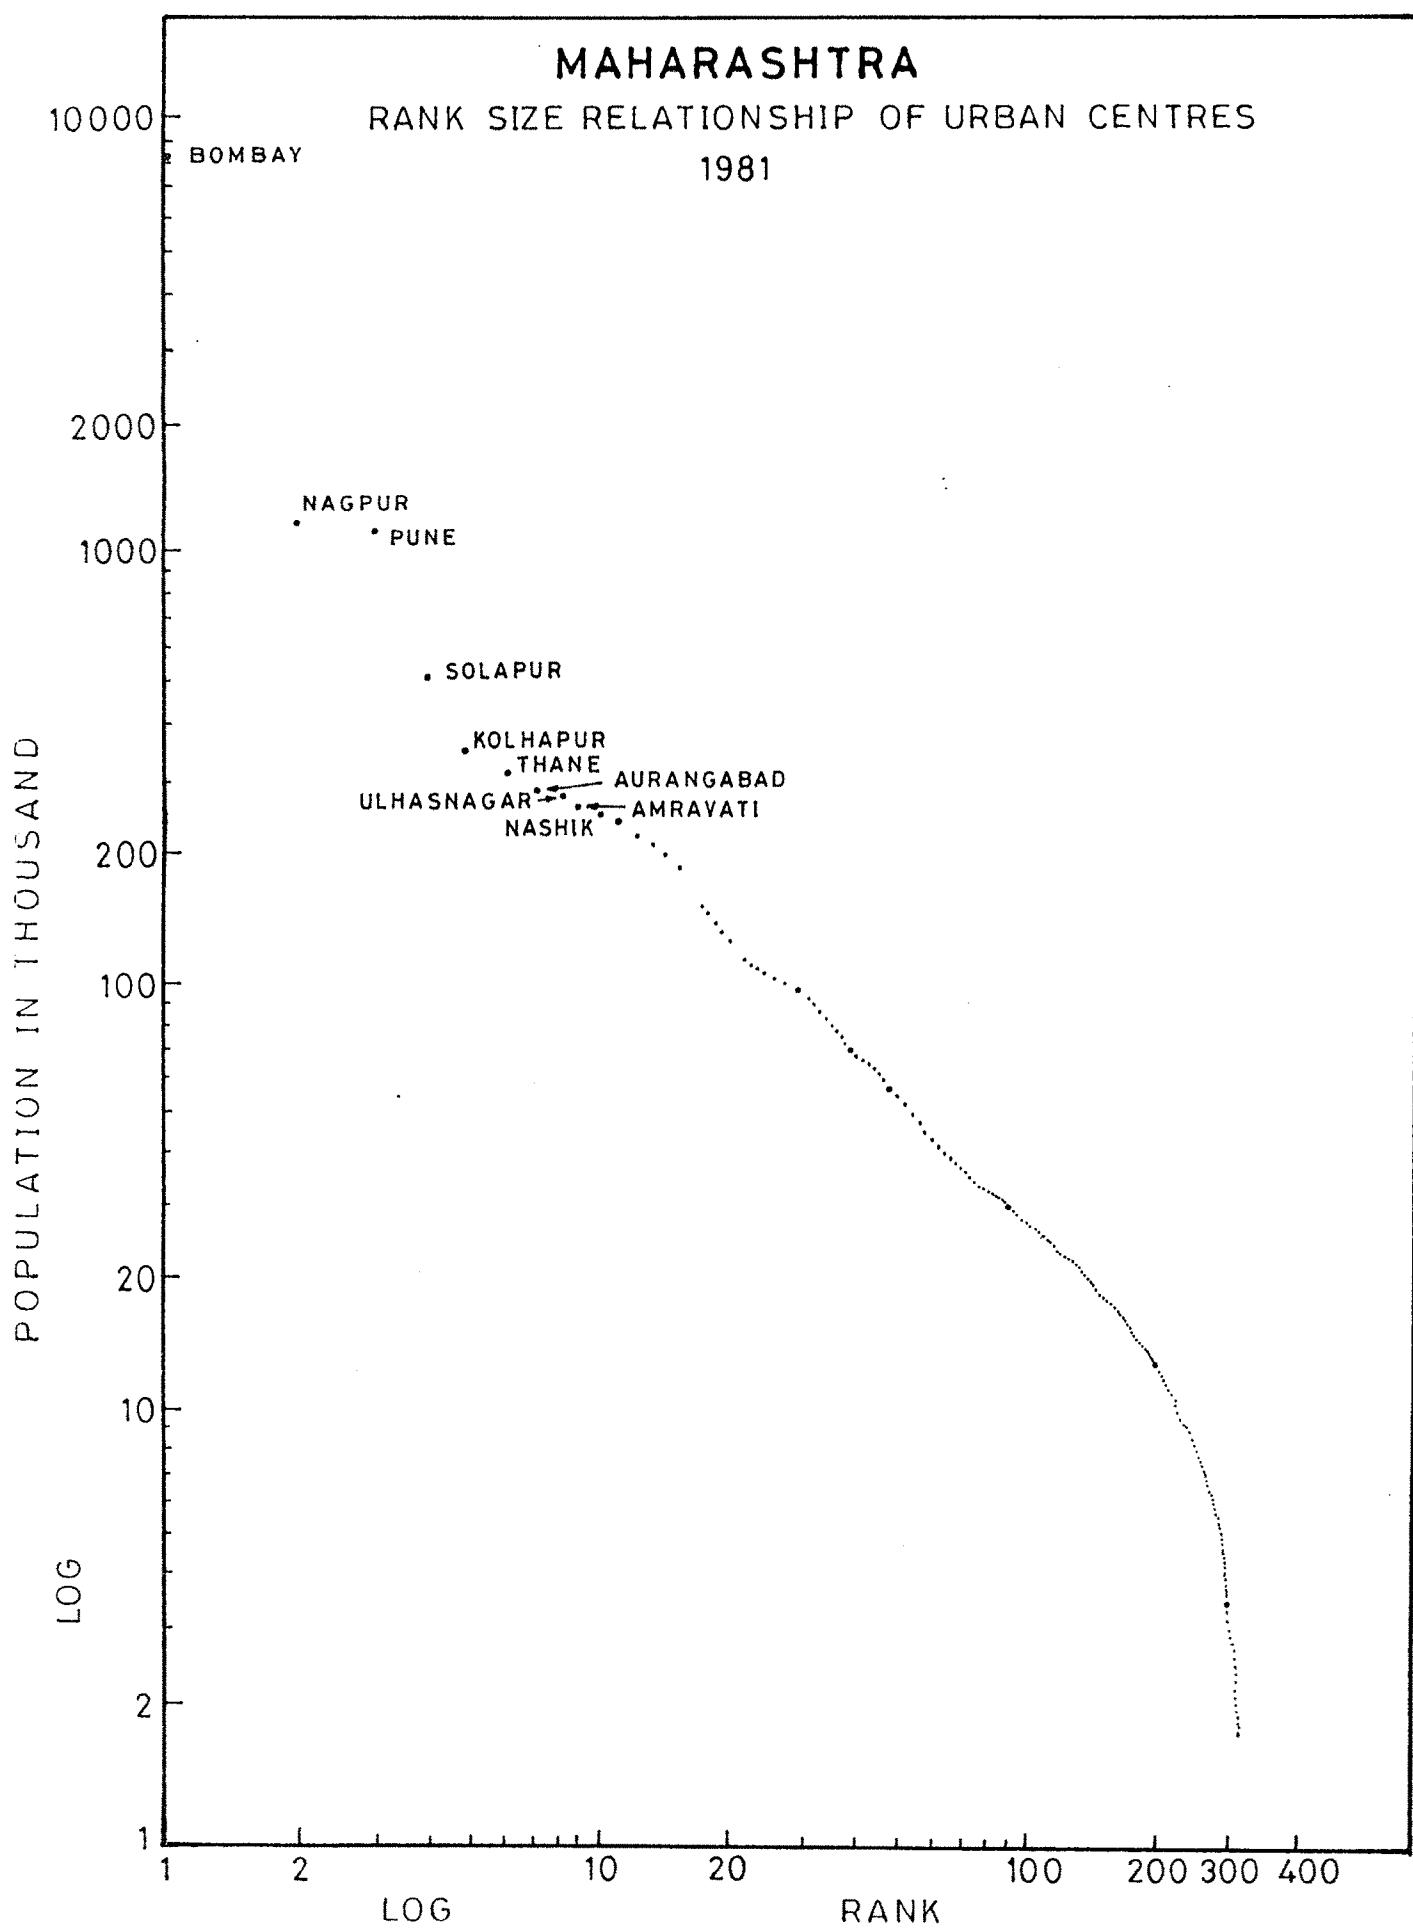

Fig. 6·1

would approximately equal to the population of the largest city. This is expressed by the equation as -

$$P_1 = \frac{P}{IR}$$

Where,
 P_1 = Population of the first city
 P = Total population of the region
 IR = Reciprocal of R

The rank size rule is an empirical observation based on the study of actual population statistics. If we examine any region it is lightly to contain many small towns, a less number of medium size town and a few large cities. This pattern of city size has been observed to be quite regular from one region to another.

There are number of ways to express the rank size relationship and deviation from it. One is to plot the rank by size of place on a Log Log scale graph. Another way is to calculate both the numbers and places and the population which would be anticipated in various size classes when compared this figures to actual distribution (Fig.6.1).

In the present study, the rank size rule has been expressed by first method. Table 6.1 illustrates the details of actual and expected population and difference between actual and expected population.

Table 6.1 : Maharashtra - Ranksize relationship (1981).

Rank No.	Name of the Urban centres	District	Reciprocal I/R	Actual population Pa	Expected population Pe

6.2 REGIONAL ANALYSIS :

The rank size rule distribution of urban centres in the State of Maharashtra when plotted on Log Log scale graph (Fig.6.1) clearly indicate that the actual population of the first rank city in the region is the larger than the expected population, in the same way the third ranking city, Pune indicates more actual population than the expected. All the remaining urban centres show less population than the expected population. In the study region the difference between actual population and expected population is found in the lower ranks of the towns. From the Table 6.1 one can observed that actual population deviations are very high. The last ranking town (Dowlameti of Nagpur district) has an actual population of 1771 persons; on the other hand the expected population of this 307 ranking centres is 11386.48 which shows nearly 85 percent deviation.

Applying the rank size rule in case of Maharashtra (using 1981 data) in this study, a graph using Log-Log scale graph exhibiting population size and the rank of towns, is represented for all the 307 urban centres. The graph clearly reveals that the rule is hardly applicable for the year 1981.
