

CHAPTER-II

KINETICS OF ION-EXCHANGE OF

Cu, Mg and Pb ,

ON

AMBERLITE IR-120

IN

AQUEOUS ACETONE AMMONIUM TARTRATE  
MEDIUM.

## INTRODUCTION

Rates of exchange can be measured in both static and dynamic systems. Although vigorous treatments relating the kinetics of ion exchange and column performance are lacking as yet, these rate measurements are of considerable aid in comparing various ion exchange systems.

It is of interest to speculate on the mechanism of exchange by considering how an individual ion in the bulk solution exchange with an ion within the resin phase. As the ion approaches the resin phase, it first diffuses through the bulk solution until it reaches a stagnant solution layer near the resin surface. It then must diffuse through this surface film. It is this film that is referred to in the film diffusion rate theory.<sup>1-5</sup> Once in the resin structure, the ion must diffuse through restricted and water-filled pores until it reaches an exchange site. At this point, exchange takes place and ion replaced covers the path taken by the entering ion. Each step of the diffusion, whether in the resin or solution phase, must be accompanied in the presence of an ion of the opposite charge, for the law of electroneutrality must be obeyed at all times. This type of diffusion is known as particle diffusion.

Kinetics of exchange reactions has been studied by many workers in aqueous media, only a few studies have been made in mixed solvents.

Turse and Rieman concluded that the rate determining step of the ion exchange reaction for several bivalent metals on Dowex A<sub>1</sub> was chemical reaction.<sup>6</sup> However, later workers could not verify this conclusion.<sup>7,8</sup>

Matsueuru and Wadachi have reported that the rate determining steps for the sorption of Co(II) and Co(III) on anion exchanger Dowex A<sub>1</sub> were particle diffusion and chemical reaction respectively.<sup>9</sup>

The differences in the conclusions concerning the rate determining step show that the kinetic studies of the ion exchange process are difficult. Attempts have been made to study the various ion exchange systems to test as to which of the mechanism are applicable.

Cation exchange chromatographic studies of manganese on Dowex 50W-X8 are recently reported in our laboratory.<sup>10</sup> The distribution coefficients for Cu, Zn, Mg, Ni, Cd, Co, Mn, Ca, Pb, Th, Al, Hg, Sr and Ba were found out in aqueous acetone - succinic acid media. The effect of varying concentrations of acetone and the acid on distribution coefficients were studied to find out the suitable conditions for the separations. The quantitative separations of manganese from other elements were carried out.

A systematic study of the cation exchange behaviour of metals on R-NH<sub>4</sub> type resin in aqueous-ammonium acetate and ammonium acetate containing other solvents (mixed media) has been reported by some workers. Minami and Ishimori<sup>11</sup> explored the possibility of separating barium from lead on a cation-exchanger by first eluting the adsorbed lead with ammonium acetate at pH 6 and then barium, with 10% ammonium chloride solution. The difference in the stability of the anionic complexes of barium

and lead with ethylenediaminetetraacetic acid at pH 4.5 and 10.5 respectively has been utilised for their separation.<sup>12</sup> Lead [pH = 4-5] passed out of bed and adsorbed barium was eluted with EDTA (disodium salt) at pH 10.5. Khopkar and De<sup>13</sup> studied the cation exchange behaviour of barium on Dowex 50W-X8 ( $H^+$ ). Nitric acid, hydrochloric acid, ammonium chloride, sodium nitrate, sodium chloride, ammonium, acetate, citric acid, tartaric acid and EDTA has been used as the eluting agents. Barium has been separated from U(VI), Cu(II), Hg(II), Cs, Zn, Cd, Ag, Ge(IV), Zr, Th, Fe(III) and Bi(III) by 4 M ammonium acetate.

#### PRESENT WORK :-

Kinetic studies of exchange reactions of Cu, Pb, and Mg ions with  $NH_4^+$  ion of Amberlite IR-120 resin in aqueous acetone ammonium tartrate media were carried out. The kinetic parameters such as interdiffusion coefficient (D), half exchange time (  $\pm 1/2$ ), parabolic diffusion constant (k), were found out. The effect of concentration of metal ions, acetone and ammonium tartrate on these kinetic parameters are reported in this chapter. The plots of  $B_t$  versus t leads to probable mechanism of diffusion. The variations of rate constant (k) with percentage of acetone and molarities of metal ions were studied. The values of energy of activation (Ea), the pre-exponential constant (Do) and entropy of activation ( S) were obtained by the studies of kinetics of exchange reactions at different temperatures.

## EXPERIMENTAL

### Solutions

1. Chloride solutions of copper(II), Lead (II) and Magnesium (II) = 0.1 M
2. Acetone % = 0, 10, 30, 50, 70 and 80
3. Ammonium tartrate 0.06 M and 0.4 M.

### Procedure

Exactly 1 g of air dried resin Amerlite-IR-120 ( $\text{NH}_4^+$ ) form was taken in an erlymeyer flask. 50 ml of mixture containing acetone water Ammonium tartrate was added. Appropriate quantity of metal ion solution was added into it at noted time so that the overall metal concentration would be 0.002, 0.0004, 0.006, 0.008 M or as desired. The change in metal ion concentration was noted at different time intervals titrimetrically.

### DISCUSSION

The kinetics of exchange of  $\text{Cu}^{2+}$ ,  $\text{Pb}^{2+}$ , and  $\text{Mg}^{2+}$ , ions on Amberlite IR-120 ( $\text{NH}_4^+$ ) resin in aqueous acetone Ammonium tartrate media was studied. The studies represent the mechanism of exchange of Cu, Mg, and Pb with the Amberlite IR-120 ( $\text{NH}_4^+$ ). The pH of the solution was observed to be more than 10 and hence the cationic complexes were formed.

### Fractional attainment of equilibrium F.

The extent of reaction, F, fractional attainment of equilibrium is expressed as

$$F = \frac{\text{The amount of exchange at time } t}{\text{The amount of exchange at infinite time}}$$

Table 2.18 Values of energy of activation ( $E_a$ ), pre-exponential constant ( $D_0$ ) and entropy of activation ( $\Delta S$ ) for Cu(II) and Mg (III) (0.004 M)(0.06 M Ammonium tartrate)

Metal ion	Acetone	$D_0 \times 10^{10}$ $m^2 Sec^{-1}$	$E_a$ kJ mol <sup>-1</sup>	$\Delta S$ J mol <sup>-1</sup> deg <sup>-1</sup>
Cu	50	3.981	32.82	- 33.25
	70	5.248	49.01	- 32.82
<sup>Zn</sup> Mg	50	1.995	32.83	- 34.31
	70	2.239	29.35	- 34.13

Now in the present case  $CV \gg \bar{CV}$  where C is the concentration of metal ion in the solution phase, V is the volume of the solution,  $\bar{C}$  is the concentration of metal ion in exchanger phase, and  $\bar{V}$  is the volume of exchanger. Thus, although the system is, in principle, a limited bath, the equation applicable to the infinite bath can be used in this case also as verified by Reichenborg,<sup>14</sup> Nelfferich<sup>15</sup> and Blickenstaff<sup>15,16</sup> in their studies. Hence,

$$F = \frac{1}{1 + \frac{\sigma}{\pi^2} \sum_{n=1}^{n=\infty} \frac{1}{n^2}} \cdot e^{-\sigma tn^2} \quad (1)$$

where

$$B = \frac{\pi^2}{r^2} D$$

r = radius of the fully swollen resin bead,

D = the effective diffusion coefficient of the two ions undergoing exchange within the exchanger, and

n = an integer having any value from 1 to 00.

The values of F are presented in Tables 2.2 to 2.11 and the behaviour of F with time t is presented by Figs. 2.1 to 2.10.

Values of  $Bt$  where  $B = \frac{\pi^2 D}{r^2}$ , were obtained corresponding to various F values using Reichenborg table R. The Bt versus t plots are shown by Figs. 2.19, 2.26 and the values of B are obtained from the slopes of these plots. The values of B are given in Table 2.12 to 2.14 and 2.17.

#### Effect of concentration of Acetone :

The values of F, fractional attainment of equilibrium

presented in Tables 2.2 to 2.11 and the graphs of F versus t give an idea of the exchange process concerned. It is observed that the half exchange time  $t^{1/2}$  decreases as the percentage of acetone increases. It indicates that the process of exchange becomes faster in presence of acetone. As per equation

$$t^{1/2} = \frac{0.03 r^2}{D}$$

$t^{1/2}$  is inversely proportional to D and hence the values of D increases with the rise in concentration of acetone. It is noted that the equilibrium period decreases with the rise in percentage of acetone. The nature of graph, F vs t, indicates the sudden rise in earlier part and becomes parallel to time axis leading towarding saturation. The greater adsorption tendencies of these metal ions on Amberlite IR-120 ( $\text{NH}_4^+$ ) are in agreement with the high values of distribution coefficients present in Tables, 3.1 to 3.4 in Chapter III.

The various factors contributing to this observation are,

- i) The swelling and solvent fractionation behaviour of  $\text{NH}_4^+$  as well as metal forms of Amberlite IR-120 ( $\text{NH}_4^+$ ) in mixed media.
- ii) the solvated size of ions in these media
- iii) Selectivities of the resin for various ions in various media, and
- iv) the viscosities of the solvent mixtures and electrolyte solutions in these solvent mixtures.

The solvated sizes of the ions under study are governed by overall solvation of the ions in specific solvent medium. In mixed solvent, cations are usually preferentially solvated by water. The extent to which the organic solvent is excluded from the solvation shell depends upon the ability of the organic solvent to solvate the cation. In this extent, a study by Zipp<sup>17</sup> shows that alkali metal cations are solvated almost equally by acetone and methanol. The similarity in the solvating tendency of these organic solvents for alkali metal ions implies that the cations in aqueous acetone or aqueous methanol solvents would have a solvation shell consisting of water molecules and, more or less, the same number of organic solvent molecules, depending upon the composition of the mixed solvent.

In the mixed systems, ionic selectivities of the resins have also been considered as a factor influencing the rates<sup>18</sup>.

The rate determining step in ion exchange is, as a rule, interdiffusion of the counter ions either in the resin itself or across the adherent liquid film. The slower of these processes controls the overall rate. In systems with organic solvents, the mobilities of the counter ions in the resin are usually lower than in aqueous systems because swelling is less pronounced and electrostatic interactions with fixed charges are stronger. Particle diffusion thus is relatively slow and usually is the rate controlling mechanism.<sup>19</sup>

The problem of diffusion in porous media is usually approached with the use of either of two rather different types

of models. In the first type, the medium is considered as consisting of two phases, namely the solid framework and the interstitial pore phase. Diffusion is viewed as taking place in the pores only. In such models, diffusion is necessarily slower than in the corresponding homogeneous systems having the same composition as the pore phase. In the second type of models, the medium is considered as a single homogeneous phase, analogous to an ordinary solution. Diffusion in ion exchange resins is assumed to be no different from that in solutions of chloride ions as analogous organic electrolytes.

#### Parabolic diffusion constant (K)

The rate determining process for most cation exchange resins is primarily the diffusion rates of the ions throughout the gel structure, and are therefore dependent on particle size, concentration, temperature, degree of saturation of exchange capacity, and resin hydration. Fractional attainment of equilibrium  $F$  is related with time  $t$  by parabolic diffusion law namely<sup>20</sup>.

$$F = K \sqrt{t}$$

where  $K$  is a constant that varies linearly with the reciprocal of the particle diameter. The values of  $K$  were obtained from slope of curves  $F$  versus  $\sqrt{t}$  presented by Figs. 2.11 to 2.18.

It is observed that the values of  $K$  are constant at a particular concentration of a metal ion and is independent on the percentage of acetone. The values of  $K$  for Cu are greater than the corresponding values of Pb in aqueous acetone 0.06 M Ammonium Tartrate media. The values of  $K$  for the exchange of Mg are found to be greater than those of Cu and Pb. This indicates that the selectivity of the resin is in the order of Cu > Pb > Mg. The same trend is observed in the studies of distribution

**coefficients in Chapter III.**

The diffusion mechanism may be decided by  $B_t$  versus  $t$  graphs. The graphs are presented by Figs. 2.19 to 2.26. It is observed that these plots are linear passing through the origin. The values of  $B$  are presented in Tables 2.12, 2.13 and 2.14. It is observed that the values of  $B$  increases with the increase in percentage of acetone, indicating that the rate of adsorption is increased at higher concentrations of acetone. These results support our results on distribution coefficients that the distribution coefficients increase at higher concentrations of acetone. The values of  $B$  follow the sequence that  $B_{Cu} > B_{Pb} > B_{Mg}$ . This sequence supports our findings of selectivity of metal ions towards the resin.

For the systems studied at various percentages of acetone, the linear nature of  $B_t$  versus  $t$  plots, passing through the origin, suggests that the rate of diffusion is controlled by particle diffusion. Some of the curves show slight deviation, at later stages, indicating that the final stage of exchange is not controlled by particle diffusion alone.

#### Effect of temperature

The exchange of  $Cu$  (0.004 M) and  $Mg$  (0.004 M) on Dowex Amberlite IR -120 ( $NH_4^+$ ) form in aqueous acetone ammonium tartrate media was studied at 308, 313 and  $318^\circ K$ . The effect of temp. on fractional attainment of equilibrium ( $F$ ), half exchange time ( $t^{1/2}$ ), interdiffusion coefficient ( $D$ ), parabolic diffusion ( $K$ )

and B values is soon from the values presented in Table 2.15 to 2.17

The variation of F versus t at 308, 313 and 318° K in 50% and 70% acetone (0.05 M) at Ammonium tartrate are presented in Figs. 2.35 to 2.38. It is observed that the uptake of Cu and Mg (0.004 M) ions is increased at higher temperatures. The amount of adsorption of Cu and Mg at 308, 313 is nearly doubled at 318° K upto 40 minutes. The comparative rates of uptake becomes slower upto 3 hrs and the rates are nearly the same after 5 hrs. It is also observed that the rate of adsorption of Cu and Mg at 70% acetone is greater than that at 50% acetone.

The values of half exchange time  $t^{1/2}$  decrease and those of interdiffusion coefficients increase with rise in temperature. It is concluded that the rate of exchange is enhanced by the temp. The energies of activation (Ea) were calculated from log D versus 1/T plots (Figs. 2.51 and 2.52) and the values are presented in Table 2.18, suggest that the rates of metal ions are activated by the energy supplied by temperature.

The values of energy of activation for  $\text{Cu}(\text{NH}_4^+)$  tart. exchanges are 32.82 and 49.01 K J mol<sup>-1</sup> at 50 and 70 percentages of acetone respectively and for  $\text{Mg}(\text{NH}_4^+)$  tart. exchanges the values are 32.83 and 29.35 K J mol<sup>-1</sup> at 50.70 percentages of acetone. The values of Ka for particle diffusion mechanism in standard ion exchange resins were found<sup>21,22</sup> to be 25.1 to 41.84 K J mol<sup>-1</sup>. The values of Ea for the systems understudy are in good agreement with the above values indicating that the exchange are mostly governed by particle diffusion mechanism.

The pre exponential constant, Do is related with the entropy of activation  $\Delta S^*$  as follows.

$$D_0 = 2.72 (K C T d^2/h) \exp (\Delta S^*/R)$$

Where  $BK$  = Boltzmann constant,  $T = 303^{\circ}\text{K}$ ,  $d$  = ionic jump (distance between two successive position of ion in the process of diffusion) taken as equal to  $5 \times 10^{-10}\text{m}$ ,  $h$  = Plank's constant and  $R$  = gas constant.

The values of entropy are found to be negative and are not measurably affected by acetone. According to Frank and Evans ionisation of natural molecules into charged species. The negative values of entropy were also observed by the behaviour of the dissociation of acetic acid in methanol<sup>23</sup>. The negative values of entropy are indeed what one would except in reactions involving ionization of neutral molecules.<sup>24</sup> Since the transformation of the outer to the inner complex involves ionization it is likely that the activated complex is also similar to ion pair, and will therefore be stabilized by solvation to a greater extent than the initial state.<sup>25</sup> The negative entropy indicates that the activated complex is less favourable<sup>26</sup>.

#### Rate constants

Log (1-F) versus time (t) for the exchange systems are plotted, and are presented in Figs 2.27 to 2.34. The plots are linear showing that the exchange systems follow the first order kinetic equation.

$$(1-F) = \exp (-Kt)$$

Where K represents the exchange rate constant. The K values for the exchange processes have been computed from the slopes of these linear plots and recorded in Table 2.12 to 2.14. The values of rate constants (K) are in agreement with the following overall relations.

- a) The rate constant 'K' increases as the percentage of acetone increases.
- b) The values of K for the metal ions in aqueous acetone citric acid are in the following sequence :

$\text{Cu} > \text{Pb} > \text{Mg}$

- c) The rate constant increases as the concentration of metal ions is increased from 0.002 to 0.0008 M solutions.
- d) The rate of ion exchange increases with the increase in temperature from  $303^\circ$  to  $318^\circ$  K (Table 2.17), suggesting that the mobility of the ion increases with increasing temperature. The uptake increases with time. These findings are similar to the findings of the distribution coefficients (chapter III) of the metal ions in these media. The distribution coefficients increases with the rise in percentage of acetone. The distribution coefficients of the metal ions showed the following order.

$K_D \text{ Cu} > K_D \text{ Pb} > K_D \text{ Mg}$
